Designing for Change: Minimizing the Impact of Changing Requirements in the Later Stages of a Spaceflight Software Project

B. Danette Allen
Langley Research Center, Hampton, Virginia

The NASA STI Program Office ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counter-part of peer reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.

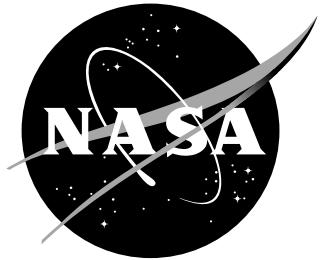

- CONFERENCE PUBLICATION. Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- TECHNICAL TRANSLATION. English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that help round out the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, see the following:

Abstract

In the traditional “waterfall” model of the software project life cycle, the Requirements Phase ends and flows into the Design Phase, which ends and flows into the Development Phase. Unfortunately, the process rarely, if ever, works so smoothly in practice. Instead, software developers often receive new requirements, or modifications to the original requirements, well after the earlier project phases have been completed. In particular, projects with shorter than ideal schedules are highly susceptible to frequent requirements changes, as the software requirements analysis phase is often forced to begin before the overall system requirements and top-level design are complete. This results in later modifications to the software requirements, even though the software design and development phases may be complete. Requirements changes received in the later stages of a software project inevitably lead to modification of existing developed software. Presented here is a series of software design techniques that can greatly reduce the impact of last-minute requirements changes. These techniques were successfully used to add built-in flexibility to two complex software systems in which the requirements were expected to (and did) change frequently. These large, real-time systems were developed at NASA Langley Research Center (LaRC) to test and control the Lidar In-Space Technology Experiment (LITE) instrument which flew aboard the space shuttle Discovery as the primary payload on the STS-64 mission. Although developed in the Ada programming language, most of these methods are language-independent and can easily be modified to be used in any high-level language.

Acronym List

AT	IBM PC AT
CAP	Command Acceptance Pattern
CDR	Critical Design Review
CFG	Command File Generator
DOD	Department of Defense
GSE	Ground Support Equipment
IC	Instrument Controller
I&T	Integration and Test
JSC	Johnson Space Center
KSC	Kennedy Space Center
LaRC	Langley Research Center
Lidar	Light Detection and Ranging
LITE	Lidar In-space Technology Experiment
MSFC	Marshall Space Flight Center
NASCOM	NASA Communications
OOD	Object Oriented Design
PIC	Payload Interface Converter
PGSC	Payload General Support Computer
POCC	Payload Operations Control Computer
SFMDM	Smart Flexible Multiplexer DeMultiplexer
SRS	System Requirements Specification
STS	Space Transportation System

1. Introduction

The Lidar In-space Technology Experiment (LITE) is a three-wavelength backscatter lidar developed by NASA Langley Research Center (LaRC) that flew on the space shuttle Discovery in September 1994 as primary payload on the STS-64 mission. Lidar (Light Detection ad Ranging) is a remote sensing technique that can be used to study clouds ad aerosols in the atmosphere by sending out short pulses of laserlight and detecting the portion scattered back to the instrument. The goals of the LITE mission were to validate key lidar technologies for spaceborne applications, to explore the applications of space lidar, and to gain operational experience which will benefit the development of future systems on free-flying satellite platforms. The 40 Gbytes of science data collected provide the first highly detailed global view of the vertical structure of clouds and aerosols from the Earth's surface through the middle stratosphere. LITE also provided the first demonstration of space lidar for study of the Earth's atmosphere and resulted in the collection of 53 hours of data, equivalent to 35 orbits of the Earth. This is the first data set that provides the highly detailed vertical structure of clouds and aerosols on a global scale. The success of the mission demonstrates the maturity of lidar technology and the potential for long-term orbital lidars on free-flying platforms. The LITE mission is detailed further in [1].

Two sets of real-time Ground Support Equipment (GSE) software were required for the development, integration, test and flight of the LITE payload. Integration and test required a real-time platform that simulated absent shuttle interfaces, displayed engineering and science data and provided a means for commanding the instrument. Mission software was required for use in the Payload Operations Control Computer (POCC) facility for commanding and data display during the flight. The software team was assembled with 18 months to develop and deliver the test GSE and, following a successful test at Kennedy Space Center (KSC), 12 months to develop and deliver mission critical ground software to Johnson Space Center (JSC) for integration into the POCC. The test GSE was developed in parallel with the instrument and was required to simulate yet-to-be-defined interfaces. The mission software would follow-on from the test software but would require major changes to accommodate new interfaces onboard the shuttle and at JSC. Both systems were developed on an accelerated schedule by small teams of three to five people. We knew we had to design for change. In order to design for change, we needed to predict what could change and when. This required that we understand why software requirements changes occur. Five change agents were identified: immature system requirements, documentation, detail comprehension, shifting user requirements and external influences. As immature external requirements were defined and new ones added, our design needed to minimize impact on the existing system. The decision was made to counter risk by driving the uncertainty into the data, as opposed to the code, through the use of external files.

The following sections will describe techniques used on these systems to build in flexibility in order to minimize the impact of late requirements changes on the software systems. A history of the LITE payload is provided for context. The disconnect between academic life cycle models and their application in our working environment is presented

along with our chosen data-driven approach. Finally, the philosophies and techniques that were successfully used in designing for change are discussed in detail.

2. LITE History

During the 10-day mission, commanding of the LITE instrument was accomplished primarily from Mission Control at JSC in Houston. All commands are received by the on-board Instrument Controller (IC), which parses the commands and relays them to the Aft Optics or Boresight Assembly subsystems, if required. The IC executes instrument level commands. The LITE instrument command set is very versatile, including over 200 commands to control every facet of the instrument operation. The LITE Command File Generator (CFG) operated without error for the entire mission duration.

The CFG is a relatively large (over 30,000 Ada statements), PC-based real-time platform from which all commands were issued to the LITE instrument during its 10-day mission. It was developed specifically for LITE and allowed for commanding the IC directly or via the Payload General Support Computer (PGSC) in the shuttle flight deck. The CFG requirements [2] are summarized in Table 1.

	Requirement	Center	Reference
1	Display relevant Payload Data Interleaver (PDI) and LITE data	LaRC JSC	
2	Retrieve instrument data from Lantastics network	LaRC	
3	Conform to NASA Communication (NASCOM) uplink format	JSC	[3]
4	Conform to Smart Flexible Multiplexer Demultiplexer command format	MSFC	[5]
5	Conform to LITE IC command format	LaRC	[4]
6	Conform to PGSC command format	MSFC	[5]
7	Interface directly to Payload Interface Converter (PIC) for uplink commands	JSC	[3]
8	Receive Command Acceptance Pattern (CAP) from PIC	JSC	[3]

Table 1: CFG Requirements

As shown in Table 1, requirements from numerous NASA centers and, therefore, numerous documents, had to be understood and merged in order to generate the CFG requirements and platform. Figure 1 shows the CFG data path.

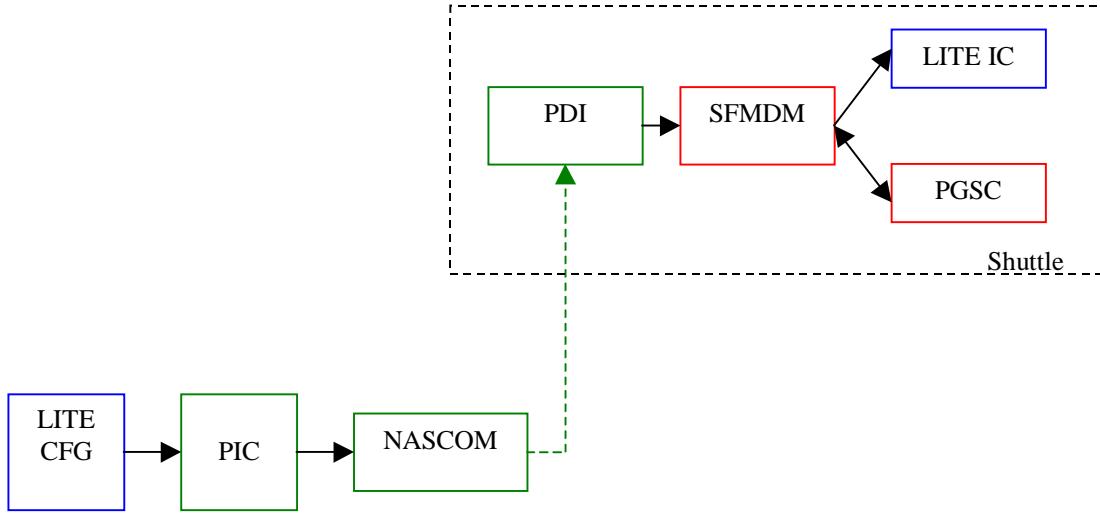

Figure 1: LITE CFG Data Path

Before any resources could be put towards the design, development and delivery of a mission commanding platform, test GSE was needed for integration and test of LITE at LaRC and KSC. Software was brought in late in the LITE project lifecycle. Any and all problems that had been hand-waved off with “we’ll take care of that in software” had to be addressed. The IC was the heart of the LITE instrument and had no formal requirements. The LITE instrument needed to be fully integrated and tested in 18 months. Test GSE development would have to be in parallel with the design of the IC software and integration of the instrument.

The Pallet Simulator (Figure 2) is a large (over 60,000 Ada statements), real-time, distributed system consisting of three platforms: Master AT, Display AT, and Quicklook AT. The Master AT interfaced directly with the LITE instrument via in-house GSE. It simulated a shuttle interface, the Smart Flexible Multiplexer Demultiplexer (SFMDM) [5], through which all commands and engineering data were transferred. For test purposes, it also provided the instrument interface for science data, again though in-house GSE. Because this platform simulated a shuttle interface, the real-time requirements of the system were its first priority and could not be compromised. These requirements were successfully married with the storage of science and engineering data along with the transfer of data to the appropriate platform, either the Quicklook AT or the Display AT. These two platforms were receive-only except for communication health checks with the Master AT and, therefore, did not interface directly with the instrument. For this reason, discussion of the Pallet simulator will be limited to the Master AT software only.

The design and development of the Master AT (IBM PC AT) software coincided with the design, integration and test of the LITE instrument. Therefore, requirements changes were inevitable. The team was forced to devise an approach that would allow for built-in system flexibility. Because the instrument was still at the subsystem level, the IC was still

at the conceptual stage. Instrument commanding and data handling were undefined. We needed autonomy but did not have an operations scenario. Little thought had been given to exactly how these items would be accomplished. What would a LITE command look like? What was the downlink data format? We had the challenge of developing a test system for an instrument that was, from a software perspective, undefined. The flight software and GSE software would be defined, designed, developed and tested in parallel alongside the instrument itself.

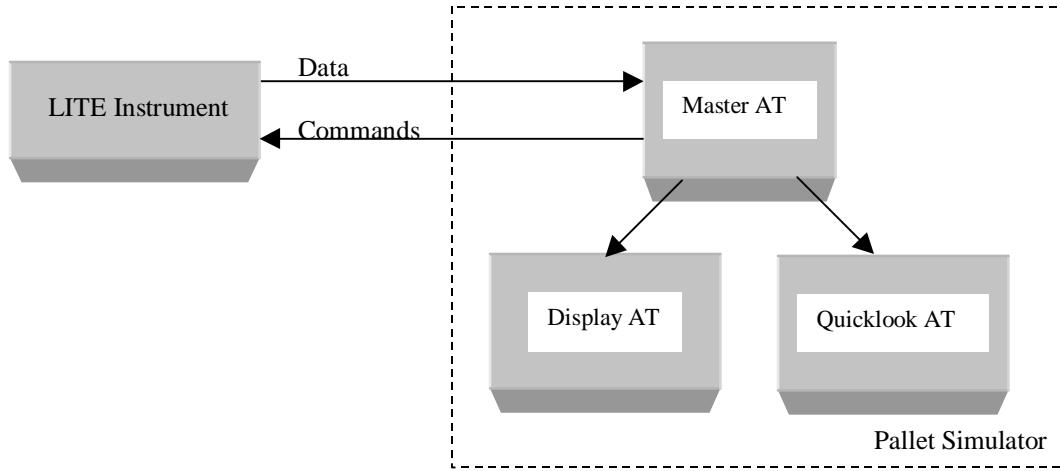

Figure 2: Master AT Architecture

The software team was faced with a challenge. The CFG would follow-on from the Master AT. The Master AT had to be delivered coincident with the semi-specified LITE instrument and the unspecified LITE IC. Figure 3 illustrates the major milestones in the LITE project timeline. Each box marks the beginning of the specified task but is not intended to communicate task duration. Of particular interest, the final System Requirement Specification (SRS) was not available until the Master AT software was delivered and the CFG software was in development.

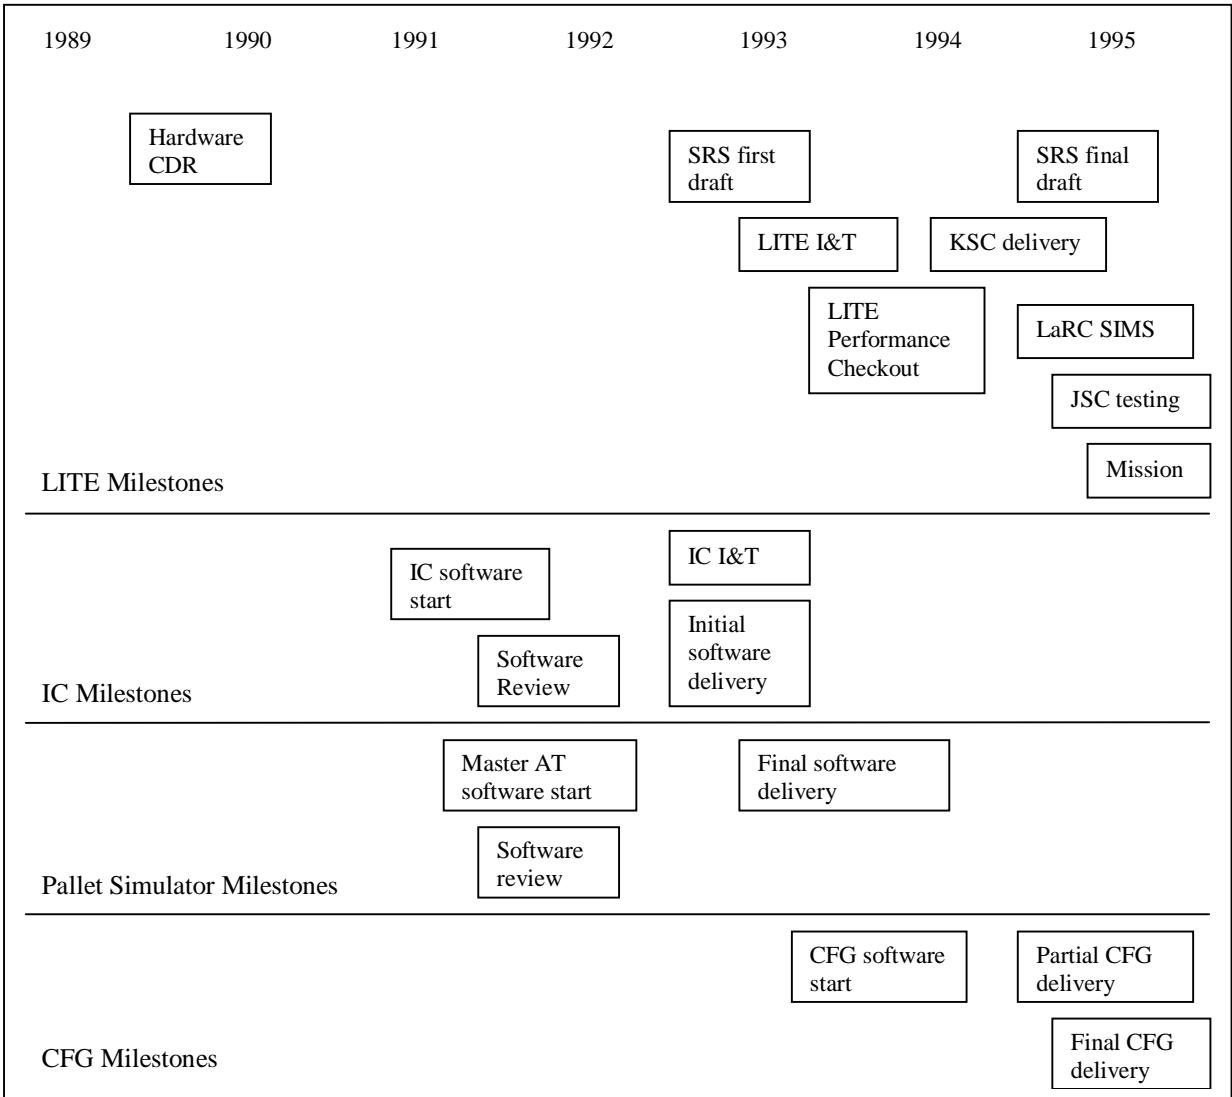

Figure 3: LITE Project Major Milestones

We needed to design and code to minimize system impacts when changes occurred. We also needed to design with reuse in mind knowing that the CFG would leverage off the Master AT development. The traditional waterfall model where all activity of a certain type occurs during a phase of the same name and in which phases do not overlap [6], was simply not an appropriate model. The spiral model requires several revolutions requiring time and experience, neither of which we had in abundance. We needed an approach suitable for the accelerated schedule under which we were to develop mission-critical GSE. Prototyping seemed the best choice but was not entirely appropriate given our short schedule and real time requirements. We combined the appropriate philosophies from several models in creating a data-driven approach that was workable within our short development schedule. We also needed to design for change. The area most susceptible to change was the data so we countered risk by using a data-driven design that generated code to accommodate changes in external text files. Presented here are the design and coding techniques used in the development of these complex platforms.

3. The Unstable Process of Software Design and Development

Change is a very natural and intrinsic aspect of the software development process. For example, change occurs [7]:

- during software requirements analysis phase, when the software requirements specification is agreed to by all parties and is baselined.
- during software development and test, when the software design, or the code, or the test plans are completed.
- during software maintenance, when requirements have changed or matured, and
- during software maintenance or later enhancement, when a problem is detected in the software requirements or system that forces modifications to the design or the code or the test plan.

Knowing that software will change is not enough. In order to design for change, one must understand why software will change.

3.1 Immature System Requirements

The trend to implement in software functions traditionally accomplished by hardware devices has led to increased size and complexity of software subsystems [18].

Historically, software has been a very small part of the total project cost and was managed as such. Older paradigms provide little or no guidance for managing software projects [8]. As a result, the need for software often goes unrecognized at the beginning stages of a project. Even once the need for software is recognized, the resources required are often underestimated, especially in the early requirements specifications and design phases. The software team regularly plays catch-up to the more mature project. However, this maturity is often limited to the subsystem level and does not apply to the system as a whole. The software team serves double duty as both software developers and system engineers [8]. In order to develop software requirements, system questions must be asked and answered. Often, these questions are first asked in the software requirements specification effort. These questions cannot always be answered immediately and, if the software team waits until the system is fully defined (all the questions are answered), schedules would never be met. As the system evolves, system requirements will change imposing new requirements on the software. However, even with a relatively stable system, the unstable process remains.

3.2 Documentation

Documentation alone is a weak communication medium [9]. CFG gathered and merged requirements from three NASA centers and four systems. Conflict among requirements is not uncommon in large systems [9] and the CFG was no exception. All PGSC commands are routed through the SFMDM. However, [5] stated that all SFMDM commands were to be 32 words in length while all PGSC commands were to be 30 words in length. This ambiguity was not uncovered until End-to-End test at JSC, very late in the project time

line. If more verbal communication had been possible earlier, this problem could have been caught while we were still developing at LaRC. The documentation could have been clarified and the problem solved much faster.

3.3 Detail Comprehension

It is impossible to see every requirement at first glance. Many of the details become known as we progress through the implementation [10]. Often one does not know the questions that need to be asked until faced with an implementation question. Even if we knew every requirement, experience shows that people are unable to fully comprehend the plethora of details that must be taken into account in order to design and build a correct system [10]. For this reason, as the picture of what is required of the software system becomes clearer, changes will occur.

3.4 User Requirements

In many cases, those who commission the building of a software system cannot specify exactly what they want nor are they able to communicate everything they know up front. There is a cultural gap between the developer and the customer [11]. The developer has the skills necessary to meet the customer requirements but does not have a complete understanding of the application while the customer has a complete view of the application but cannot know the capabilities of the software. This is often the case with mission GSE. The user specifies that a system is needed for commanding or to display science data. Often, little thought has been given to exactly what the user wants to see and how the user will interact with the system. Scientists and engineers are busy at the subsystem level while the software developers are working at the system level. Software prototyping has been proposed as a solution to this problem and the generation of a strawman concept is useful in minimizing the impact of changing user interface requirements. However, we found that there is a limit to how far ahead a system can be prototyped. No amount of prototyping can predict the wants and wishes of the users once the system is integrated, new system hot spots have been discovered and the community of users changes.

3.5 External Influences

Because software is intangible, it is constantly subject to pressures for change [12]. This can be due to “creeping elegance”, an altered interface, “planned” flexibility, or the need to fix a system problem. In any case, no traces are cut, no connectors demated, and, usually, flight configuration is not broken when a software change is made. Software can be viewed as infinitely malleable and an inexpensive fix since it can be changed “more easily” than hardware. To some degree, this is true, especially in the later phases of the project life cycle. When external interfaces change, the software is often expected to change in order to accommodate the new requirements. When a new capability of deemed necessary, software is often expected to provide this functionality.

4. Software Development Approaches

Three widely accepted approaches to software development are the waterfall life cycle model, the spiral life cycle model and prototyping. While we recognized the merit of these schemes, careful examination proved that no single one of them would meet our needs given the immature system requirements and the accelerated project schedule. We selected the most fitting aspects from these well-documented models to create an approach that suited our development environment.

4.1 Waterfall

The waterfall model consists of five basic stages (requirements analysis and definition, system and software design, implementation and unit testing, system testing, operations and maintenance) and assumes that one stage ends before the next stage begins [13]. In the typical flight software development environment, strict adherence to waterfall development methodologies is impossible [14]. The uncertainties of high-level requirements definition and significant hardware and spacecraft interface design changes well into the software development cycle would prevent ever evolving out of the software requirements phase. This was the case during the development of the Pallet Simulator Master AT. If we had waited until all requirements were firm before moving on to the design phase, we would have had nothing but requirements to show on the designated delivery date.

4.2 Spiral

The spiral model [15] is a risk-driven approach that emphasizes prototyping and incremental and iterative deliveries and allows a more realistic approach to requirements satisfaction than the traditional waterfall models [16]. Each iteration around the spiral passes through four phases (Planning, Risk Analysis, Engineering, Customer Evaluation) as progressively more complete versions of the software are built. It attempts to combine the best elements of the waterfall model and prototyping while recognizing and providing a mechanism for risk analysis. In that, the spiral model demands considerable risk assessment expertise and we simply did not have the time or the expertise to fully implement the spiral model development approach.

4.3 Prototyping

Software prototyping enables the developer to create a model of the software that must be built. It is especially helpful in the requirements specification phase [11]. Because we had a set of general objectives for the GSE software but little detailed information about input, processing, and output requirements, prototyping seemed the best modeling choice, especially for gaining insight into the user interface. However, we did not have the time to implement a pure prototyping life cycle. We could not afford to throw away precious development time along with the models themselves. However, prototyping would enable us to create a model of the software that, at a minimum, would simulate the user-machine interface. This “strawman” approach worked well. It defined what the user interface

should look like and we were able to extract other system requirements. In GSE, very little processing is performed that is not displayed in one form or another. Prototyping led to a top-down function design process that meshed well with the real-time context. The first “quick design” prototype was a throw-away. After a look and feel was agreed upon, we moved to a data driven approach.

4.4 *Data Driven Approach*

Many real-time system developers feel that present-day software engineering methods are insufficient to meet the needs of real-time programming [17]. Data flow-oriented techniques are generally seen as the best fit method for real-time system design. Functional decomposition makes it easy to cope with some peculiar aspects of real-time systems such as concurrency and timing requirements [18]. For non-embedded applications like the CFG, prototyping is helpful in designing the user interface from which requirements inevitably fall out. We found this to be true in the Pallet Simulator development but wanted a more modular design for the CFG. Due in part to the language selection (Ada), the design of the Master AT was inherently modular enough to allow for reuse of packages whose functionality would be required later (i.e. LITE command block construction) but we knew we could improve on that with the CFG. In general, functional oriented methods are stronger in the early stages of software design in going from requirements to top-level design elements. We carried over this philosophy to the CFG but used an Object Oriented Design (OOD) approach at the package level. Our high-level requirements were functional in nature and mapping the CFG requirements back to the mission requirements was simple. We defined objects to represent the interfaces and data definitions that required further clarification. This enabled us to isolate the code that we knew would change, as requirements were refined and system changes impacted current requirements. This helped in driving the changes into the data but was not sufficient. We did not want to perform a system rebuild every time a data definition changed. External data files could be used to provide dynamic data definition. The following narrates the design decisions and techniques used to minimize risk by pushing the system uncertainty into the data.

5. **Design Techniques**

The selected language for flight and ground software development was Ada. Ada facilitated the use of a number of design techniques such as information hiding, data abstraction and modularity. These techniques were successfully employed in the generation of several reusable packages for menuing, operating system isolation and data display.

5.1 *Ada Language Choice*

Ada was developed in the early 1980’s as the mandated language of the Department of Defense (DOD) and as a potential solution to the rising cost of software development. NASA LaRC had not mandated the use of Ada in its flight projects but the organization responsible for the LITE software was in the process of establishing a center-wide

standard for software. The software engineer on LITE selected Ada as the language best suited for real-time system development at LaRC for both embedded and non-embedded environments. Ada was not specifically manufactured to support object oriented design. Nevertheless, some of its features like data and processing abstraction, generic types, packages (that support information hiding), are particularly useful in implementing object oriented design. The “package” is an important Ada concept. Inherent in the use of the Ada package is a certain degree of modularity. Even though OOD was not used in the development of the Master AT, all of the functions also needed by the CFG system could be ported directly over with only a few modifications. Ada was especially useful in the design phase of the CFG. The design was a team effort with individual responsibilities assigned to each member. During the design, specifications for all packages were created and compiled. These specifications imported other specifications so we were able to group blocks and subsystems before any processing code was created. Package bodies were created with procedure and function stubs. The coding phase simply filled in these functions and procedures one by one. Integration and test was simplified in that we already had a system in place. We needed only to verify functional correctness. Ada promotes software engineering better than any other modern language [19]. The package concept, strong typing and Ada compiler helped us enforce our software interfaces and imposed a modular design on both systems. Adherence to the Ada philosophy inherent in the language provided modularization, abstract data types and hierarchical structuring [12].

5.2 *Modularity*

Modularity has a direct positive impact on maintainability [18]. To this end, the design of the CFG system was modular in nature. At the top level, functional decomposition separated logical modules. Within each functional module, objects were separated through the use of packages using an OOD approach. A high-level architectural block diagram can be found in Figure 4. Due to immature requirements during the initial design phase, we often did not know the exact definition of that data that was to be passed from module to module. We knew the size of the data but the format was yet to be determined. To work around this problem, we were forced to override one of the features of Ada, strong typing. To simplify parameter passing to and from procedures, all parameters were passed as arrays of unsigned bytes. Unchecked Conversion allowed for the integration of many different data types used within individual packages. When the data definitions were defined, the existing procedures and functions were overloaded to handle both the primitive data (unsigned byte) and the strongly typed data type.

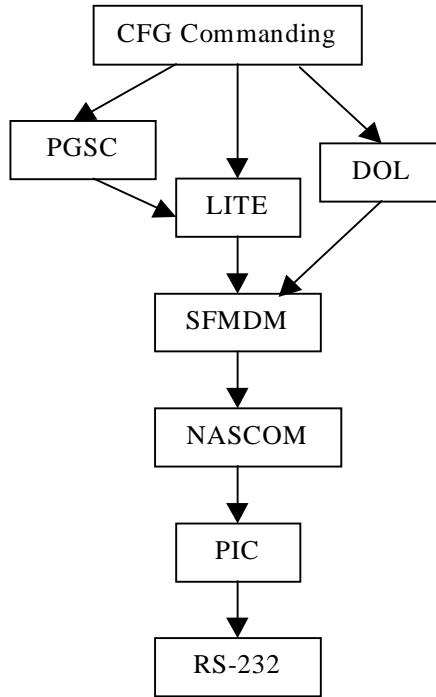

Figure 4: Partial CFG Architecture

5.3 Abstraction and Information Hiding

Information hiding focuses on what to hide; abstraction focuses on what to reveal. The principle of information hiding is that each module (or package) hides a design decision and implementation. If the design decision changes later, then no calling code should need to change. It is the other side of the coin from data abstraction [20]. Abstract data types should make it possible to change the data representation of objects while guaranteeing that all visible operations on the objects have the same properties. Procedural abstraction can be used to obtain much of the effect of abstract data types. A data structure can be defined and a set of procedures can be written to manipulate that data [21]. In Ada, data abstraction is often accomplished through the use of generic packages. In the CFG development, abstraction was achieved through procedures for ease of testing. Generic packages presented difficulties in the test and debug phase of software development. The inline debuggers could not see inside an Ada generic. Further, in Ada 83, generics were highly inefficient in memory usage and reclamation at execution time.

The Menu Package (Appendix 1) is one example of data abstraction and information hiding used in the software. It provides a text-based menuing facility that was developed for the user interfaces on both the Master AT and CFG platforms. Neither system had graphics displays requirements. Therefore, text-based menuing and data display was chosen for speed and executable size advantages. With the Menu Package, vertical menus were defined, displayed and read via the limited private type `Menu_Type` and the

procedures and functions provided for operations on a menu object. Menus are defined by procedure `Define_Menu` using upper left and lower right coordinates, color scheme, title, and border style. The parameters are read from an input file specified by the calling routine. This is an excellent example of information hiding. The programmer creates a text file that contains all the information required to define a menu and declares an object of type `Menu_Type` with no need to know exactly what this type looks like. Procedures and functions are provided for access information about the menu.

`Get_Menu_Coordinates`, `Get_Menu_Color_Scheme`, `Get_Menu_Border_Style` and `Get_Menu_Title` are examples of the procedural data abstraction used in providing operations on the `Menu_Type`. `Read_Menu` returns the sequence number of the selected item in the menu specified. Other operations are `Append_Item`, `Insert_Item`, and `Delete_Item` that allow menu modification during program execution.

While the Menu Package was created specifically for menuing, we also used it during the prototyping phase of development. Menu parameters can be defined such that no highlighted selection bar is present and dummy data can quickly and easily be placed on the screen with calls to `Define_Menu` and `Display_Menu`. Data can then be moved around on the screen and colors changed with a simple modification to the input text files with no required recompilation, bind or link. This is discussed in more depth in Section 5.7.

5.4 *Filename Manager Package*

The Filename Manager Package allowed greater flexibility in naming external files such as data files, initialization files, and menu definition files. It allowed the code to use identifier strings, called "tags", to select files, instead of being limited to the file naming restrictions imposed by the host operating system. In addition, it also prevented literal file names from being "hard-wired" into the code. This allowed us to change file names, or use a substitute file with a different name in a test, without having to modify or re-compile the code. It also provided operating system independence.

An input file is created that contains a list of data pairings, the actual file name and its associated file tag. A pairing in an input file appears as

```
[CFG_Command_Logfile]  
[C:\CFG\LOG\COMMAND.LOG]
```

where the file tag `CFG_Command_Logfile` is mapped to the actual file `COMMAND.LOG` in directory `C:\CFG\LOG\`.

The actual file names are assigned when the file is read in at list initialization. This allows complete code isolation from the operating system. It also allows for easy testing of new data files. The filename input file can be modified to associate a different file name with an existing file tag and the new file name will be used. No modifications are required to an existing working file so nothing is lost in testing the new data definition.

The following functions are available operations on the private type

`Filename_List_Type` that is a record that contains the filename list and the length of the list. Private type `File_Node_Type` defines the list contents as a record that holds the file tag, the actual filename to which the tag maps and a pointer to the next list element. The private type declarations are listed below. Filename Manager Package, in its entirety, can be found in Appendix 2.

```

TYPE Filename_List_Type IS
  RECORD
    Length      : NATURAL := 0;
    Node_List   : File_Node_Access_Type;
  END RECORD;

TYPE File_Node_Type;
TYPE File_Node_Access_Type IS ACCESS File_Node_Type;
TYPE File_Node_Type IS
  RECORD
    File_Tag     : Variable_String_Package.VString;
    Filename     : Variable_String_Package.VString;
    Next        : File_Node_Access_Type;
  END RECORD;

```

The overloaded function `Get_Filename` searches the specified list for the file tag or tag position passed to it and returns the actual file name associated with that tag. A mapping is created with procedure `Generate_Filename_List` that requires a filename list and an actual filename, `From_File`, which can be passed in as a result of the function `Get_Filename`. File tags can be retrieved with function `Get_File_Tag` based on a file name or position and specified list. Careful file management allows the position returned to be used in combination with the Menu Package choice in `Read_Menu`. Pairings can be removed from the set by either file name or file tag with procedures `Delete_File_Name` and `Delete_File_Tag`, respectively. Pairings can be inserted via procedures `Append_To_Filename_List` or `Insert_Into_Filename_List`. Procedure `Insert_Into_Filename_List` inserts the new pairing in sorted order, assuming a sorted list, by either file name or file tag as specified in the parameter `Insert`. Sorted mappings are achieved through procedure `Sort_Filename_List` which sorts by either file tag or filename. Procedure `Save_Filename_List` allows the user to save the current contents of a filename list to an external file so that runtime changes to a list are not lost. If `Save_Filename_List` is not called at shutdown, the original file from which the list was created will remain intact.

5.5 External Initialization Files

A big challenge for the Master AT development was lack of command and data definition. The data size had been determined, as had the maximum command size. However, little consideration had been given to the command and data format. Additionally, the LITE subsystems were not yet completed, further complicating command definition. Even once the basic command format was defined, the command codes themselves were still changing. Each LITE serial command had a unique associated 8-bit identifier when

coupled with the 2-bit command subsystem destination. Three initialization files were created - one for each subsystem destination. At runtime, these files were read in and the command database was initialized from these files. As the subsystem command codes were defined, we needed only to edit the external text files in order to accommodate the system changes.

5.6. *Constants Package*

Figure 5 illustrates the evolution of the Constants Package concept used in both the Master AT and CFG systems. The following sections explain the refinement of this package that can be found in its entirety in Appendix 3.

5.6.1. Specification only. While developing the Pallet Simulator and CFG software, the team noticed that many constants and objects were needed in several packages resulting in multiple declarations. For example,

```
Byte_size : constant integer := 8;
```

appeared in almost every package body developed. If a requirements change effected any of these variables, the domino effect would have been significant. Our solution was the Constants Package that was used in both systems. A package Specification was created to isolate shared data definitions. Theoretically, this makes maintenance easier in that a change in one place will trickle down through the entire software system. However, there was one major drawback. While changes were isolated, a complete system rebuild was required whenever a change to the constants package was made. Many packages WITHed in the constants specification and had to be recompiled whenever the constants package specification was recompiled.

5.6.2. Specification and Body (Package) with function calls. In order to avoid a recompile of the entire system when a data definition changed, the existing constants package Specification was modified. Each object in the Specification was redefined as a function whose name was identical to the existing object name. No code modifications of existing software were required since the object to function translation was transparent to the calling code. The data values were defined as constant declarations in the package body. If a data definition changed, all that was required was a constants package body recompile which did not necessitate any further recompiles. All that was required was a new BIND and, as with the constants specification concept, the changes trickled down through the software. This was an improvement over the original specification only package but still did not isolate the risk to the data exclusively.

5.6.3. Package with initialization files. In order to eliminate recompiles entirely, the constants package body was further refined. At runtime, an initialization file was read in. All constant declarations were changed to object declarations. The objects declared were defined at runtime with the contents of the initialization file. With this modification, data definition changes could be affected with no compilation, no bind and no link of the system. The code was data independent and, as much as possible, data definition changes

were isolated to simple ASCII text files.

5.6.4. Package with initialization files and filename manager package. The final modification to the Constants Package was for OS isolation. The filename manager package was used in opening, reading and closing the initialization file. While this change did not increase data isolation, it was in keeping with the OS-independent design approach.

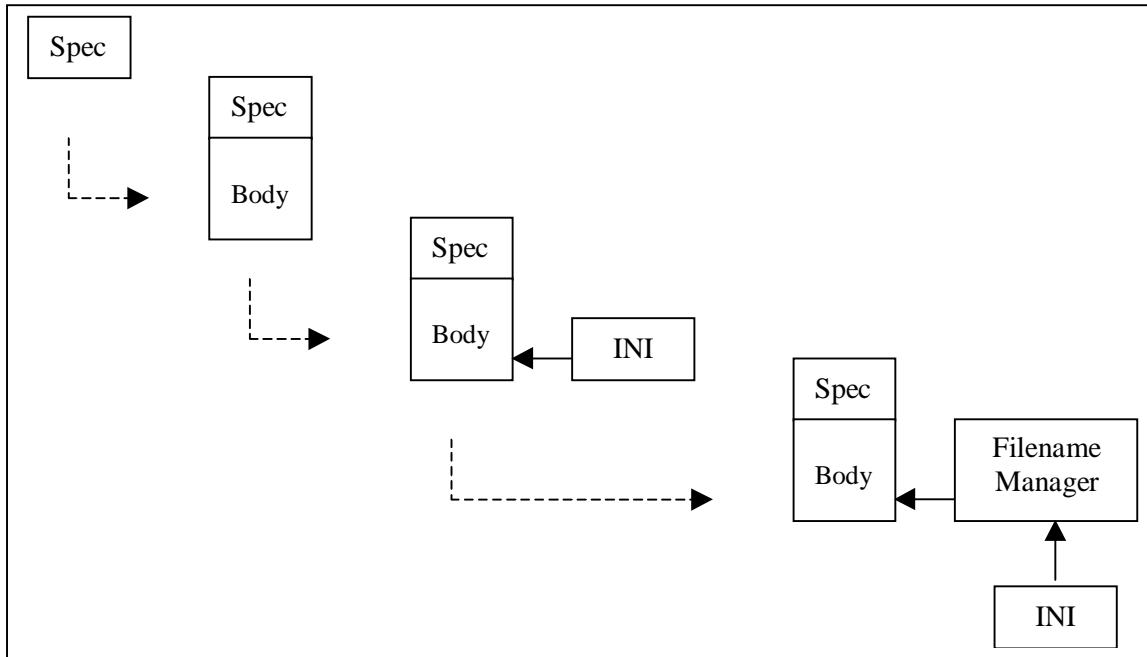

Figure 5 : Evolution of Constants Package

5.7. *Relative Positioning*

Relative referencing combines the data abstraction and information hiding illustrated by the Menu Package with the data-driven design approach of initialization files. The prototyping efforts accomplished with the Menu Package were so successful that we wanted to incorporate this idea into the delivered product. With the prototype, dummy data was used for display purposes. Static displays were sufficient for conveying the look and feel of the user interface. We needed a way to handle periodic, dynamic data for the working systems in both the test and mission environments and accomplished this through relative positioning of data. Menu files were used to define the placement, size and color of a data block. For example, a window to display command tracking is illustrated in Figure 6.

```
Commands sent from CFG:  
Commands rejected by MCC:  
SFMDM Input command counter:  
SFMDM Command reject count:  
Invalid Uplink Commands:
```

Figure 6: Command Count Data Window

This window can be created with a text file that contains the information in Figure 7.

```
[ ]          -- Menu Title  
[0]          -- initial value of Current_Item  
[2]          -- Upper Left Row  
[2]          -- Upper Left Column  
[8]          -- Lower Right Row  
[30]         -- Lower Right Column  
[Blue_Background]      -- Background Color  
[Yellow_Foreground]    -- Foreground Color  
[Yellow_Foreground]    -- Title Color  
[Light_Cyan_Foreground] -- Border Color  
[Bright_White_Foreground] -- Highlight Color  
[Single]        -- Border Type  
  
***** Menu Items *****  
  
[0]          [Commands sent from CFG:]  
[0]          [Commands rejected by MCC:]  
[0]          [SFMDM Input Command Counter:]  
[0]          [SFMDM Command Reject Count:]  
[0]          [Invalid Uplink Commands:]
```

Figure 7: Command Count Window File

Defining and displaying the data blocks was simple. We needed a way to update the data that was equally as simple and flexible. Relative positioning was the solution to this. The Command Count Window was defined as a menu:

```
Command_Count_Window : Menu_Package.Menu_Type;
```

Objects were declared to hold the row and column positions of the window.

```
Command_Count_Window_Top_Row,  
Command_Count_Window_Bottom_Row : Screen_Package.Row_Type;  
Command_Count_Window_Left_Column,  
Command_Count_Window_Right_Column:Screen_Package.Column_Type;
```

At start-up, the menu is defined using the Filename Manager Package to avoid the use of OS-specific file names and reduce recompilations.

```
Menu_Package.Define_Menu  
(The_Menu => Command_Count_Window,  
 Item_List => Command_Count_Window_List,  
 Filename =>  
     CFG_Filename_Package.Get_CFG_Filename  
     (CFG_List => CFG_Filename_Package.MENU,  
      File_Tag => Command_Count_Window_File_Tag));
```

The menus coordinates are assigned after the external file is read in and the coordinates are defined.

```
Menu_Package.Get_Menu_Coordinates  
(Command_Count_Window,  
 Command_Count_Window_Top_Row,  
 Command_Count_Window_Left_Column,  
 Command_Count_Window_Bottom_Row,  
 Command_Count_Window_Right_Column);
```

At this point, the cursor positioning for data updates is entirely relative to the coordinates read in from the external menu file.

```
Screen_Package.Position_Cursor  
(Row => Command_Count_Window_Top_Row + 1,  
 Column => Command_Count_Window_Right_Column - 5);
```

Changes to the menu file will be reflected in all data updates and data placement can be easily altered without any system changes.

6. Conclusions

LITE flew as the primary payload on STS-64 in September of 1994. It is the first lidar system to be operated in space and the first to use lasers in space for study of the Earth's atmospheric environment. It provided the most accurate measure of cloud top heights to date and provided data on the depth and structure of cirrus and other thin clouds. The success of LITE has provided new information on the distribution and characteristics of clouds to increase our understanding of their role in the global climate system. The LITE instrument CDR was held in April of 1989. A software team was formed in late 1990 to

develop systems to support integration and test, and mission. These real time systems were developed under a tight schedule and, despite the late start, with immature system requirements. Steps had to be taken to incorporate flexibility into the support software. We had no choice but to design for change.

One of the clearest lessons in this discussion about “design for change” is that one must anticipate changes before one begins the design [22]. System architecture changes in the later stages of a software project are dangerous, costly, and common. In order to avoid system architecture changes, the areas of the software most likely to change must be identified and consideration given to why they will change. This process illuminates how requirements will change and methods for accommodating these changes can be designed into the deliverable. Life cycle modeling attempts to capture this process but required unavailable resources such as personnel and time. The software team developed a data driven approach to development that incorporated aspects of several models. In both software systems developed for LITE, data was the most likely target for change. Information hiding, low intermodule coupling achieved through modular design and object-oriented development were key in limiting the impact of requirements changes. Additionally, we attempted to build in modifiability by pushing the elements we knew would change out of the code into external files and designing for dynamic data definitions.

Acknowledgments

The author gratefully acknowledges fellow CFG and Master AT software development team members Kerry M. Gough and Mark A. Parks. The author is also grateful to Michael L. Nelson whose careful reviews of this paper have improved its clarity and readability.

Appendix 2: Filename Manager Package

```
-----  
-- File Name:      FNAMEMGR.ADS  
-- Organization:   NASA - Langley Research Center (LaRC)  
-- Project:        LIDAR In-Space Technology Experiment (LITE)  
-----  
-- ****  
-- Name/Number:  
--     Filename_Manager_Package           (package spec)  
--  
-- Abstract:  
--     This package is used to allow greater flexibility in naming external  
--     files such as data files, initialization files, menu definition files,  
--     and so on. It allows the code to use identifier strings, called "tags",  
--     to select files, instead of being limited to the file naming restrictions  
--     imposed by the host operating system. In addition, it also prevents  
--     literal file names from being "hard-wired" into the code. This allows  
--     the programmer to change file names, or use a substitute file with a  
--     different name in a test, without having to modify or re-compile his  
--     code.  
--  
-- Acronyms/Abbreviations:  
--     None  
--  
-- Dependencies:  
--     None  
--  
-- Global Objects:  
--     None  
--  
-- Exceptions:  
--     Duplicate_Filename  
--     Duplicate_Tag  
--     Invalid_File  
--     Invalid_Filename  
--     Invalid_File_Contents  
--     Invalid_Position  
--     Invalid_Tag  
--  
-- Machine/Compiler Dependencies:  
--     None  
--  
-- ****  
  
WITH Variable_String_Package;  
PACKAGE Filename_Manager_Package IS  
  
-----  
--  
-- VISIBLE TYPES  
--  
-----  
-- file name/tag list type  
TYPE Filename_List_Type IS PRIVATE;  
  
-- When writing a filename list to an external file, this enumerated type  
-- allows a calling routine to have control over the desired type of  
-- file I/O action. When generating a filename list from an external file  
-- it allows the calling routine have control over the type of action  
-- taken on the input list.  
TYPE List_Action_Type IS (Overwrite,  
                         Append);
```

```

-- This enumerated type is used in the procedure that Sorts a list.
-- It allows the calling routine the choice of reordering the
-- list either by tag or name.
TYPE List_Sort_Type IS (By_File_Tag,
                        By_Filename);

-----
-- VISIBLE EXCEPTIONS
--

-----  

-- When searching a list for a file tag, this exception is raised if the
-- file tag is not found
Invalid_Tag : EXCEPTION;

-- When searching a list for a filename, this exception is raised if the
-- filename is not found
Invalid_Filename : EXCEPTION;

-- This exception is raised when a new file tag to be added to a
-- filename list already exists in that list.
Duplicate_Tag : EXCEPTION;

-- This exception is raised when a new filename to be added to a
-- filename list already exists in that list.
Duplicate_Filename : EXCEPTION;

-- This exception is raised when a list position passed to a function does
-- not exist.
Invalid_Position : EXCEPTION;

-- This exception is raised when a problem is encountered with opening
-- or creating an external file
Invalid_File : EXCEPTION;

-- This exception is raised when a problem is encountered while getting
-- token pairs from an external file. The problem may be a token that
-- is too long ( > 80 chars) or a token may be missing
Invalid_File_Contents : EXCEPTION;
-----  

-- VISIBLE FUNCTIONS
--  

-----  

-- This function returns the number of nodes in a filename list.
--  

-- Inputs:  

--   Filename_List : input list whose number of nodes (tag/filename pairs)
--                  is to be returned
-- Outputs:  

-- Exceptions:  

-----  

FUNCTION Length_Of

```

```
(Filename_List : IN      Filename_List_Type) RETURN NATURAL;
```

```
-----  
--  
-- This procedure clears (deallocates) the input list  
--  
-- Inputs:  
--   Filename_List : input list to be cleared  
--  
-- Outputs:  
--   Filename_List : cleared null list to return  
--  
-- Exceptions:  
--  
-----
```

```
PROCEDURE Clear_Filename_List (Filename_List : IN OUT Filename_List_Type);
```

```
-----  
--  
-- This procedure allows the user to save the current contents of a  
-- filename list to an external file. If the Action is "Append",  
-- then the tag/filename pairs in the list are appended to the end of the  
-- To_File, empty or not. In this case, if the input list happens to  
-- be null, the file will remain unchanged. If the Action is "Overwrite"  
-- and the file is not empty, then the tag/filename pairs will overwrite  
-- the contents of the file. In this case, if the input list happens  
-- to be null, the file will be empty afterwards.  
--  
-- Inputs:  
--   Filename_List - tag/filename list to be written from  
--   To_File       - external output file for which to write the  
--                   tag/filename pairs  
--   Action         - action to take on file, either append or overwrite  
--  
-- Outputs:  
--  
-- Exceptions:  
--   Invalid_File - raised when there is a problem with the external  
--                  file open or creation  
-----
```

```
PROCEDURE Save_Filename_List (Filename_List : IN      Filename_List_Type;  
                             To_File      : IN      STRING;  
                             Action       : IN      List_Action_Type);
```

```
-----  
--  
-- This procedure is used to create a new list of filenames and tags.  
-- It reads the filenames and the tags  
-- from an external file. If the Action is  
-- "Overwrite", the list will be overwritten with the new entries found in  
-- the From_File. If the Action is Append, the tag/filename pairs found  
-- in the given From_File will be appended to the list. The From_File  
-- is checked for duplicate file tags and filenames and exceptions raised  
-- when necessary.
```

```

-- 
-- Inputs:
--   Filename_List - tag/filename list to be manipulated
--   From_File      - external file from which to read the tag/filename
--                      pairs and put int the Filename_List
--   Action          - action to take on list, either append or overwrite
--
-- Outputs:
--   Filename_List - tag/filename list to be manipulated
--
-- Exceptions:
--   Invalid_File_Contents - raised when an expected token can not
--                          be found in the external file or
--                          if a token is too long ( > Max_Token_Length)
--   Invalid_File        - raised when there is a problem with the
--                         external file open or creation
-----
PROCEDURE Generate_Filename_List
    (Filename_List : IN OUT Filename_List_Type;
     From_File    : IN      STRING;
     Action       : IN      List_Action_Type);

-----
-- 
-- This procedure allows the user to add a new file tag/filename pair to
-- the end of the filename list. Duplicate tags and filenames are not
-- allowed and raise the Duplicate_Tag or Duplicate_Filename exceptions.
--
-- Inputs:
--   Filename_List - tag/filename list to be add to
--   File_Tag      - file tag to be added to list end
--   Filename       - filename to be added to list end
--
-- Outputs:
--   Filename_List - tag/filename list after addition of new pair
--
-- Exceptions:
--   Duplicate_Filename - raised when the input filename is found to
--                       already exist in the list
--   Duplicate_File_Tag - raised when the input file tag is found to
--                       already exist in the list
-----
PROCEDURE Append_To_Filename_List
    (Filename_List : IN OUT Filename_List_Type;
     File_Tag     : IN      STRING;
     Filename     : IN      STRING);

-----
-- 
-- This procedure allows the user to do a "sorted" insert of a new
-- file tag/filename pair into the filename list. The pair will be
-- alphanumerically inserted either by file tag or by filename. The
-- routine assumes that the list is already properly sorted for the
-- desired insert. Results will be unpredictable if either the list
-- is not already sorted or if the pair is inserted by the wrong
-- token (tag or name). Duplicate tags and filenames are not
-- allowed and raise the Duplicate_Tag or Duplicate_Filename exceptions.
-- 
```

```

-- Inputs:
--   Filename_List - tag/filename list to be add to
--   File_Tag      - file tag to be added to list end
--   Filename       - filename to be added to list end
--   Insert         - insert type (by file tag or filename)
--
-- Outputs:
--   Filename_List - tag/filename list after addition of new pair
--
-- Exceptions:
--   Duplicate_Filename - raised when the input filename is found to
--                       already exist in the list
--   Duplicate_File_Tag - raised when the input file tag is found to
--                       already exist in the list
-----

-----
-----

-- This procedure is used to create a new list of filenames and tags.
-- "Generate_Filename_List", reads the filenames and the tags associated
-- with them from a file to build a filename list. If the Action is
-- "Overwrite", the list will be overwritten with the new entries found in
-- the From_File. If the Action is Append, the tag/filename pairs found
-- in the given From_File will be appended to the list. The From_File
-- is checked for duplicate file tags and filenames and exceptions raised
-- when necessary.
--
-- Inputs:
--     Filename_List - tag/filename list to be manipulated
--     From_File     - external file from which to read the tag/filename
--                      pairs and put into the Filename_List
--     Action         - action to take on list, either append or overwrite
--
-- Outputs:
--     Filename_List - tag/filename list to be manipulated
--
-- Exceptions:
--     Invalid_File_Contents - raised when an expected token can not
--                           be found in the external file or
--                           if a token is too long ( > Max-Token_Length)
--     Invalid_File         - raised when there is a problem with the
--                           external file open or creation

13. ABSTRACT (Maximum 200 words) In the traditional "waterfall" model of the software project life cycle, the Requirements Phase ends and flows into the Design Phase, which ends and flows into the Development Phase. Unfortunately, the process rarely, if ever, works so smoothly in practice. Instead, software developers often receive new requirements, or modifications to the original requirements, well after the earlier project phases have been completed. In particular, projects with shorter than ideal schedules are highly susceptible to frequent requirements changes, as the software requirements analysis phase is often forced to begin before the overall system requirements and top-level design are complete. This results in later modifications to the software requirements, even though the software design and development phases may be complete. Requirements changes received in the later stages of a software project inevitably lead to modification of existing developed software. Presented here is a series of software design techniques that can greatly reduce the impact of last-minute requirements changes. These techniques were successfully used to add built-in flexibility to two complex software systems in which the requirements were expected to (and did) change frequently. These large, real-time systems were developed at NASA Langley Research Center (LaRC) to test and control the Lidar In-Space Technology Experiment (LITE) instrument which flew aboard the space shuttle Discovery as the primary payload on the STS-64 mission.
